Prof. (Dr.) M. Abdul Rahiman Pro Vice Chancellor Kerala Technological University

Abstract—Steganography is a technology used since years for the communication of messages secretly. These secret messages are put inside honest carriers. Carriers can be digital images, audio files, video files and so on. The limitation in sending concealed longer messages has been overcoming by the inclusion of video files as carriers. Popular internet services such as Skype, BitTorrent, Google Suggest, and WLANs are targets of information hiding techniques. Nowadays, plotters are not only using the carriers but also the protocols for communication that regulate the path of the carrier through the Internet. This technique is named Network Steganography.

Keywords- Protocol Steganography; Network Steganography; Cryptography

I. INTRODUCTION

The term Steganography originates from the ancient Greek words steganos – covered, concealed or protected and graphein – writing. Likewise, the term cryptography originates from kryptos – hidden or secret and graphein [1]. Steganography and cryptography can be applied in combination; both are orthogonal [2]. Both the terms have closer meaning. But both need to be considered as different techniques for hiding information.

Network steganography is a fast developing field and immature branch of information hiding [3]. Krzysztof Szczypiorski at Warsaw University of Technology introduced network steganography and a steganographic method for wireless local area networks (WLANs) - Hidden Communication System for Corrupted Networks, HICCUPS. The gist of network steganography is the exploitation of Open System Interconnection Reference Model (OSI RM) protocols. Wojciech Mazurczyk and Krzysztof Szczypiorski published the first paper about network steganography in Internet Protocol telephony, introducing the concept of Lost Audio Packet Steganography, LACK.

The classification of network steganography methods can be based on the protocol functions associated with the OSI RM layers. These methods utilize one or more protocols simultaneously. The steganographic method that utilizes single network protocol is termed Intra-protocol network steganography and the one which utilizes more than one network protocol is termed Inter-protocol network steganography [1]. Padding Steganography (PadSteg) is one of the inter-protocol steganographic methods.

The classification of intra-protocol network steganographic methods is based on the type of modification of Protocol Data Unit (PDU) and modification of timerelations between PDUs. There exists methods which encompass the modification of PDUs as well as the modification of time-relations between PDUs, such methods are considered"hybrid" [10] e.g. LACK, and Retransmission Steganography (RSTEG). Modification of PDUs includes either modification of payload, modification of protocol specific fields (e.g. Wireless Padding (WiPad), specific methods of Stream Control Transmission Protocol (SCTP)) or both (hybrid, e.g. HICCUPS), while the modification of timerelations between PDUs includes either reordering of the PDUs by SCTP multistreaming based methods, intentional losses of PDUs or modification of inter-PDU time delay.

Section II of this paper discusses the evolution of Steganography. Section III discusses the recent develop- ments in the field of network steganography. Section IV discusses various network steganography methods. Section V briefs the future possible applications and Section VI concludes the discussion.

II. EVOLUTION OF STEGANOGRAPHY

Steganography, meaning hidden writing, has been used to mask secret messages. In olden days, physical or ordinary objects were selected as carriers for hidden information [9]. The first written report of the Steganography use is imputed to the Greek historian Herodotus. It involved disguising the secret message within a hare corpse. The physical object or the carrier had to be shifted from one communication party to the other without arising any hunch.

Histiaeus tattooed secret message on the shaved head of his slave and waited for the hair to grow. The slave is sent to the intended receiver and the head was shaved off to read the message. Another noteworthy method used is the use of wooden tablets for the communication of secret messages [3], [9]. These were coated with a layer of wax. The woods were the carrier of the stenograms. Only the cognizant receiver would be able to read the message by removing the wax coated. Pliny the Elder invented the sympathetic ink or invisible ink which is nothing but the milk of the tithymalus plant. The messages written by this ink would appear only when it is heated. Other steganographic methods used in ancient days include Cardano Grille - a stiff sheet perforated with rectangular holes, Vexierbild - picture puzzle, Eggs, Beer barrel - by smuggling messages inside the stopper, Musical notes - each note corresponds to a letter, Newspaper code - by punching holes above letters, combination of invisible ink and musical notes and Microdots - by shriveling text down to a dot [3], [9]. In the 1980s, user identities were encoded in the spaces between words, termed watermarking. Today's steganographic methods make use of computers and networks. The most popular trends in digital steganography are digital media Steganography, linguistic Steganography and network Steganography [9]. Digital media steganography includes image Steganography, video Steganography and streaming Steganography. Alongside these, the one target of increased interest is the network Steganography.

III. RECENT DEVELOPMENTS

Recent information hiding solutions exploit popular P2P services like Skype, P2P file sharing systems like BitTorrent, search features like Google Suggest, multimedia and real-time services like IP telephony, new network protocols like SCTP, wireless network environments and many more [2].

Steganographers exploit services if it has large volume of traffic that can be altered to bring forth a covert channel (e.g. IP telephony). Transcoding Steganography (TranSteg) is a steganographic method which targets IP telephony services. Another steganographic method, Skype Hide (SkyDe) targets P2P services like Skype. A steganographic method has been introduced for P2P file sharing services, StegTorrent. The StegSuggest steganographic method targets the feature, Google Suggest.

Wireless networks are very popular, dynamically evolving network steganography sub-field. Information hiding techniques target wireless networks also. WiPad, a stegano- graphic method for WLANs, was introduced by Mazurczyk and Szczypiorski.

IV. NETWORK STEGANOGRAPHIC METHODS

The following are the existing network steganograhic methods.

A. HICCUPS

HICCUPS stands for Hidden Communication System for Corrupted Networks. It is the steganographic system dedicated to shared medium networks including WLANs. The freshness of HICCUPS is the use of procure communications network fortified with cryptographic mechanisms to provide steganographic system and proposal of a new protocol with bandwidth allocation based on corrupted frames [13]. It is a steganographic system for hidden group with common knowledge. A station sends a corrupted frame, i.e., a frame with an incorrect checksum. Remaining hidden stations change their mode of operation to the corrupted frame mode. To transmit steganograms, HICCUPS replaces payload of intentionally corrupted frames at the transmitter [10].

B. LACK

LACK stands for Lost Audio Packet Steganography. It is the steganographic method which targets IP telephony. There exists a fact that in typical multimedia communication protocols (e.g. Real-time Transport Protocol (RTP)), overly detained packets are not used by the receiver to rebuild the transmitted data. Those packets are reckoned useless and did cast away [14]. To transmit steganograms, LACK replaces payload of intentionally delayed voice packets at the transmitter. And those packets will be recognized as lost and dropped at the receiver [10]. The steps are:

- The voice packets stream is generated at the transmitter.
- One of the voice packets is chosen to be intentionally delayed.
- Chosen voice packet's payload is replaced with steganogram and it is delayed.
- After the delay timer expires, delayed voice packet is sent to the receiver.
- Usual receiver treats excessively delayed voice packet as lost and it drops such packet.
- LACK-aware receiver extracts steganogram from delayed voice packet.

C. RSTEG

RSTEG stands for Retransmission Steganography. RSTEG is a new steganographic method which is meant for a wide class of protocols that uses retransmission mechanisms. The main novelty in RSTEG is that it does not acknowledge a packet which is received successfully, thereby intentionally invoking its re-transmission. Instead of user data in the payload field, the retransmitted packet carries a steganogram [12]. In RSTEG, to transmit steganograms, the receiver intentionally does not acknowledge received packets to invoke retransmission. The sender replaces the payload with the secret message which is recognized as a steganogram by the receiver.

One possible detection method is statistical steganalysis based on the network retransmission rate. RSTEG is very hard to detect, if it is used reasonably [10].

D. SCTP Multistreaming-based Method

SCTP is Stream Control Transmission Protocol. SCTP improves by mixing components of TCP and UDP. In this method, subsequent chunks are transmitted within streams determined by bits of steganogram. Let the steganogram be 10011100 and let there be 4 streams - Stream 1, 2, 3 and 4 [10]. The steps are:

- Sender wants to transmit following hidden bits: 10011100.
- First two hidden bits are 10, so a chunk within stream 3 is sent.
- Next a chunk within stream 2 is sent in order to transmit bits 01.
- Then a chunk within stream 4 bits 11.
- Finally a chunk within stream 1 bits 00.

E. PadSteg

PadSteg stands for Padding Steganography. It is the steganographic system for LANs. PadSteg is known to be the first inter-protocol steganography solution. By the term interprotocol, it means the usage of relation between two or more protocols from the TCP/IP stack to enable secret communication [10].

PadSteg replaces padding bits of the short Ethernet frames with steganograms. The known Etherleak vulnerability makes PadSteg not trivial to detect. Etherleak is caused by ambiguous standardization that makes implementation of padding mechanism vary. In result, some NIC drivers handle frame padding incorrectly and fail to fill it with zeroes [4].

PadSteg utilizes Address Resolution Protocol (ARP) to identify all PadSteg-capable hidden nodes and also to perform so called carrier-protocol hopping during hidden exchange. Carrier-protocol hopping is an ability to negotiate carrier-protocol of the steganograms during hidden communication.

PadSteg actually exchanges data with short frames of protocols such as Transmission Control Protocol (TCP), ARP, User Datagram Protocol (UDP) and Internet Control Message Protocol (ICMP).

F. TranSteg

TranSteg (Trancoding Steganography) is a middlingly new IP telephony steganographic method.

It functions by compressing open data to make space for the steganogram. This is achieved by means of transcoding. It offers high steganographic bandwidth. TranSteg retains good voice quality. It is harder to detect than any other VoIP steganographic methods that exist today. In TranSteg, the hidden information is extracted and the speech data is practically restored to what was originally sent, after the steganogram reaches the receiver. This is a brobdingnagian advantage when TranSteg is compared with the existing VoIP steganographic methods. In all other methods, hidden data can be extracted and removed, but the original data cannot be restored because it was previously erased due to a hidden data insertion process [15].

TranSteg is intended for a broad class of multimedia and real-time applications e.g. IP telephony. TranSteg can be exploited in other applications or services like video streaming, wherever a possibility exists to efficiently compress the overt data. The typical approach to steganography is to compress the covert data in order to limit its size, because it is reasonable in the context of a limited steganographic bandwidth [10]. TranSteg utilizes compression of the overt data to make space for the steganogram. TranSteg for IP telephony is using transcoding of the voice data from a higher bit rate codec - overt codec to a lower bit rate codec covert codec with the least possible degradation in voice quality.

TranSteg operates as follows:

- For a chosen RTP voice stream, find a codec that will result in a similar voice quality but smaller voice payload size than the originally selected.
- Then, transcode the voice stream.
- At this step, the original voice payload size is intentionally unaltered and the change of the codec is not indicated.
- Instead, after placing the transcoded voice payload, the remaining free space is filled with hidden data.

If Secure Real-time Transport Protocol (SRTP) is utilized for RTP streams, TranSteg detection is very difficult to perform.

G. SkyDe

SkyDe stands for Skype Hide which is a new steganographic method. SkyDe uses Skype-encrypted silent packets to provide means for secret communication. Skype does use any silence suppression mechanism. Therefore, it is possible to reprocess those packets that have no voice signal, for steganographic purposes. SkyDe experiments prove that the method is viable. Also, results show that SkyDe offers high steganographic bandwidth.

Voice over IP (VoIP) or IP telephony is a real-time service. It enables users to make phone calls through data networks that use an IP protocol. One of the most popular of the IP telephony systems is Skype. It is a proprietary P2P telephony service. Skype is owned by Microsoft [5]. Because of Skype traffic encryption, SkyDe can replace the encrypted silence with encrypted secret data. This makes SkyDe hard to detect. Packets with silence have low impact on Skype conversation quality. To provide undetectability and low voice quality distortion SkyDe that utilizes 30% of all packets with silence is advised [10]. This gives almost 2 kbits steganographic bandwidth.

H. StegTorrent

StegTorrent is a new network steganographic method. It is intended for the popular P2P file transfer service - BitTorrent. StegTorrent is developed for encoding classified data or information in transactions via BitTorrent. It works on the basis of reordering data packets in the peer to peer data exchange protocol. Some of the existing steganographic methods also reorder packets, but they need synchronization. StegTorrent doesn't.

BitTorrent is a P2P file sharing system that allows its users to distribute large amounts of data over IP networks [6]. A BitTorrent user shares a file or part of a file with so many recipients at once. This is the advantage taken up by StegTorrent. [7]

In the clandestine communication scenario, both the secret data senders and receivers are in control of a number of BitTorrent clients and their IP addresses are known to each other. It is not at all necessary to have any knowledge about the topology of the network. The hidden data sender uses the modified BitTorrent client, i.e., the StegTorrent client. This client then shares a resource downloaded by another StegTorrent client. And that consists of a controlled group of BitTorrent clients [6].

I. StegSuggest

StegSuggest is the steganography method that targets Google Suggest. Google Suggest service's suggestions within Google search are utilized as a hidden data carrier.

Google Suggest was created to aid a user bump the right phrase by suggesting and completing popular phrases automatically while typing. StegSuggest is another approach to attack Google searches. Google Suggest is based on Asynchronous JavaScript and XML (Ajax) technology. It brings up a list of 10 most popular related search phrases as the user types. It integrates Document Object Model (DOM), HTML/XHTML, Cascading Style Sheets (CSS), Extensible Markup Language (XML), JavaScript etc. Web applications that uses Ajax can retrieve data from the server asynchronously. This retrieval will neither disrupt the display nor behavior of the page which is loaded currently.

One attack intercepts the suggestions from Google server. It adds a word to the end of each of the suggested phrases [11]. The hidden receiver extracts these appended words and then converts it into a meaning message with the aid of a pre-shared lookup table. Google Suggest uses HTTP and TCP protocols. Both of them have been used for exchanging web pages. StegSuggest works as follows:

When user begins typing a search phrase into the search field, once in a while, these characters are sent to the Google server in HTTP GET message [8]. Google server returns a list of the most popular search phrases in HTTP OK message. The list is then presented to the user in a drop-down list. While the user is typing, HTTP GET messages are sent frequently. This means that during search for particular phrase, numerous HTTP messages will be exchanged. Each HTTP request may carry at least one or more characters of the search phrase.

V. FUTURE APPLICATIONS

Network Steganography has a lot of future applications for malicious software. The application of the aforementioned network steganographic methods leads to more sophisticated malware. The covertness of malevolent programs on smart phones can be increased in the future. This possibility is dramatically doubled in smart phones because the multimedia capability lets to create and use a video range of carriers e.g. audio, video, images or Quick-Response (QR) codes. Another reason is the availability of a full featured TCP/IP stack. It gives the possibility to interact with desktop- class services, thereby completely utilizing all the already available network methods for computing devices. Also, covert channels can be made exploitable based on VoIP and P2P, since the plethora of the adopted OS allows developing sophisticated applications. Network Steganography has been emerging into new and new domains. The stealthiness of ille- gal data exchange can be increased. Network Steganography can have tremendous influence to industrial espionage when it comes to data leakage.

VI. CONCLUSION

Network Steganographic methods are getting more sophisticated. They are becoming harder to detect. New and new data carriers could be developed. It must be highlighted that as new and popular steganographic methods evolve, the data traffic of genuine internet users will also be utilized by network steganograhers. The network steganography threat can affect all internet users. This would lead to legal as well as ethical problems. Recently, there has been a significant increase in the development and application of network steganographic methods for malicious purposes. This in turn has increased the qualities, capabilities and covertness of the network steganography. Network steganography would be applied in an increasing manner in each and every future malware or malicious activities. But, there lacks effective countermeasures. Therefore, an additional research is a critical need in the field of network steganography which would formulate universal countermeasures.

ACKNOWLEDGEMENT

The author would like to thank her guide, Mr. Manoj Kumar G., Associate Professor, LBS Institute of Technology for Women, Thiruvananthapuram and Prof. (Dr.) M. Abdul Rahiman who encouraged her throughout the preparation of this paper.
